19 No. 60/466,799 entitled "Low-profile-core and thin-core optical waveguides and  
20 methods of fabrication and use thereof" filed 04/29/2003 in the names of David W.  
21 Vernooy, Joel S. Paslaski, and Guido Hunziker, said provisional application being  
22 hereby incorporated by reference as if fully set forth herein.

## BACKGROUND

**[0002]** The field of the present invention relates to semiconductor optical devices. In particular, etched-facet semiconductor optical devices including integrated optical waveguides are described herein.

**[0003]** Various optical devices might include a semiconductor optical device and an integrated end-coupled waveguide formed on a common substrate. Spatially selective material processing is typically employed to form the semiconductor optical device on a semiconductor substrate. Additional spatially selective material processing steps are typically employed for forming the integrated waveguide (which may comprise different materials, such as silica or other low-index materials) on the semiconductor substrate. The accuracy that may be achieved using spatially selective material processing enables sufficiently accurate spatial mode matching and transverse alignment for achieving end-coupling efficiency at or above operationally acceptable levels for many optical device applications. Set forth hereinbelow are a variety of structures, and spatially selective material processing sequences for forming them, for optical devices and integrated end-coupled waveguides. Spatially selective material processing may be employed for forming concurrently multiple optical devices with corresponding integrated waveguides on a common device substrate.

## SUMMARY

**[0004]** An optical apparatus comprises a semiconductor optical device waveguide formed on a semiconductor substrate, and an integrated end-coupled waveguide formed on the semiconductor substrate. The integrated waveguide may typically comprise materials differing from those of the device waveguide and the substrate, including silica, silica-based materials, other glasses, silicon nitride and oxynitrides, polymers, other low-index materials, and so on. Spatially selective material processing may be employed for first forming the optical device waveguide on the substrate, and for subsequently depositing and forming the integrated end-coupled waveguide on the substrate. Spatially selective material processing techniques enable sufficiently accurate spatial mode matching and transverse alignment of the device waveguide and integrated waveguide. Multiple device waveguides and corresponding integrated end-coupled waveguides may be fabricated concurrently on a common substrate by spatially selective material processing on a wafer scale.

**[0005]** The integrated end-coupled waveguide may be adapted for fulfilling one or more functions, including (but not limited to): transfer of optical power between the optical device and an optical transmission component through the integrated waveguide, by end-coupling or side-coupling; spatial mode matching; modal index matching; adiabatic side coupling; spatial mode control/modification; optical frequency control/modification; and so on. The end face of the device waveguide and/or the proximal portion of the integrated waveguide, and/or spatially selective material processing steps for forming the same, may be adapted in a variety of ways for achieving the needed/desired degree of end-coupling between the device waveguide and the integrated waveguide. Such adaptations may include (but are not limited to): providing a laterally expanded device waveguide end face for enhanced optical surface quality; providing a curved and/or tilted device waveguide end face; providing optical coating(s) for the device waveguide end face; providing a transversely flared device waveguide end segment for increasing transverse mode size and thereby decreasing diffractive loss; providing reflective coating layer(s) between the substrate and the integrated waveguide for reducing optical leakage into the substrate; reducing or substantially eliminating segments of the waveguides lacking substantially complete

1 transverse optical confinement; reducing or substantially eliminating any integrated  
2 waveguide material deposited on the device waveguide end face; and so on.

3 **[0006]** Objects and advantages associated with etched-facet optical components with  
4 integrated end-coupled waveguides may become apparent upon referring to the  
5 disclosed exemplary embodiments as illustrated in the drawings and disclosed in the  
6 following written description and/or claims.

16 sequence for forming an integrated waveguide.

17 **[0038]** Fig. 33 illustrates an exemplary spatially selective material processing  
18 sequence for forming an integrated waveguide.

19 **[0039]** Fig. 34 illustrates an exemplary spatially selective material processing  
20 sequence for forming an integrated waveguide.

21 **[0040]** Fig. 35 illustrates an exemplary spatially selective material processing  
22 sequence for forming an integrated waveguide.

23 **[0041]** It should be noted that the relative proportions of various structures shown in  
24 the Figures may be distorted to more clearly illustrate the present invention. Relative  
25 dimensions of various optical devices, optical waveguides, optical fibers, optical  
26 components, optical modes, alignment/support members, grooves, and so forth may be  
27 distorted, both relative to each other as well as in their relative transverse and/or  
28 longitudinal proportions. In many of the Figures the transverse dimension of an optical

- 1 element is enlarged relative to the longitudinal dimension for clarity, which will cause  
2 variations of transverse dimension(s) with longitudinal position to appear exaggerated.
- 3 **[0042]** The embodiments shown in the Figures are exemplary, and should not be  
4 construed as limiting the scope of the present invention as disclosed and/or claimed  
5 herein.

## DETAILED DESCRIPTION OF EMBODIMENTS

**[0043]** An exemplary embodiment of a semiconductor optical device and an integrated end-coupled optical waveguide 200 is shown in Figs. 1A/1B. The optical device and waveguide 200 are each shown as a planar waveguide on semiconductor substrate wafer 102. For forming the semiconductor optical device, a series of semiconductor layers are deposited, grown, and/or otherwise formed on a semiconductor substrate wafer 102. These layers may include a device functional layer 104 between upper device layer 106 and lower device layer 108. Device functional layer 104 may provide active and/or passive optical device functionality. Upper device layer 106 and lower device layer 108 may each include one or more semiconductor layers adapted in any suitable manner for providing substantial optical confinement of device optical modes in vertical directions, and for applying drive or control signals to device functional layer 104 for providing active optical device functionality (if such active functionality is present). In some instances lower device layer 108 may simply comprise substrate material, with no actual boundary between layer 108 and substrate 102. Substantial optical confinement in vertical directions may be achieved in a variety of ways, including but not limited to: index contrast between layer 104 and layers 106 and/or 108, single-layer and/or multi-layer reflection from layers 106 and/or 108, and so on. Upper and lower device layers 106/108 may be substantially identical, or may differ (in thickness, index, material(s), and/or structure) depending on the particular requirements for the optical device.

**[0044]** Spatially selective material processing steps of any suitable type are employed for providing substantial optical confinement of device optical modes in lateral directions, thereby forming a device planar waveguide structure 100. Substantial optical confinement in lateral directions may be achieved in a variety of ways, including but not limited to: index contrast between medial and lateral portions of layers 104, 106, and/or 108; physical and/or chemical modification of medial and/or lateral portions of layers 104, 106, and/or 108; removal of lateral portions of (i) an upper portion of layer 106, (ii) layer 106 and an upper portion of layer 104, (iii) layers 106 and 104 and an upper portion of layer 108, or (iv) all of layers 104, 106, and 108 (as in Figs. 2A/2B/2C); replacement of lateral layer portions thus removed with lower-index lateral cladding material; single-layer and/or multi-layer reflection from coatings applied to lateral

1 surfaces of the device waveguide 100; substantially surrounding portions of the device  
2 waveguide 100 with lower-index media (including vacuum, air, inert gas, encapsulation  
3 media, and so forth); gain guiding by spatially-selective current injection into a  
4 semiconductor laser gain medium; and other suitable means. Spatially selective  
5 material processing steps of any suitable type may be employed for forming an end face  
6 at one or both ends of the device waveguide 100 (only one end face is shown in Figs.  
7 1A/1B and 2A/2B/2C). In Figs. 2A and 2B, the end face 120 is shown formed by simple  
8 termination of the end of device waveguide 100. In Fig. 2C, the end face 120 is shown  
9 adapted for providing improved planarity. The spatially selective material processing  
10 steps employed for providing lateral optical confinement and for providing the device  
11 end face(s) may be concurrent or sequential. Multiple semiconductor optical devices  
12 may be fabricated concurrently on a common semiconductor substrate.

13 **[0045]** End face 120 of the device waveguide 100 is formed using spatially selective  
14 material processing steps, particularly such steps as may be implemented on a wafer  
15 scale prior to dividing the wafer into bars or into individual device chips. An end face  
16 thus formed may also be referred to herein as an etched facet or an etched end face,  
17 although etching processes may comprise only one group among many spatially  
18 selective material processing techniques suitable for forming the end face. Use of the  
19 terms "etched facet" or "etched end face" should not be construed as limiting the scope  
20 of the present disclosure and/or appended claims to only end faces formed by etching.

21 **[0046]** In some instances it may be necessary or desirable to provide an optical  
22 coating on end face 120, between device waveguide 100 and integrated end-coupled  
23 waveguide 200. Once end face 120 has been formed on device waveguide 100, one or  
24 more optical coating layers 122 may be applied thereto prior to fabrication of an  
25 integrated end-coupled waveguide 200. Such coating layers are applied using spatially  
26 selective material processing, and may be applied on a wafer scale to the end faces of  
27 many device waveguides simultaneously. Deposition of coating layer(s) 122 onto end  
28 face 120 typically results in deposition of coating material(s) on adjacent areas of  
29 substrate 102 and the top of the device waveguide 100 (Fig. 3A). If this is the case, it  
30 may be necessary or desirable in some circumstances to remove (by suitable additional  
31 spatially selective material processing steps) these adjacent areas of coating material

1 (Fig. 3B) prior to fabrication of the integrated end-coupled waveguide 200, particularly  
2 coating material deposited on substrate 200. In other circumstances these additional  
3 coating areas may be left intact, and the coating material(s) on substrate 200 may be  
4 incorporated into a proximal end of the integrated end-coupled waveguide 200 upon its  
5 fabrication.

6 **[0047]** Once device waveguide 100 and end face 120 have been formed using  
7 spatially selective material processing techniques, and coating layer(s) 122 (if any)  
8 applied to end face 120, an integrated end-coupled planar optical waveguide 200 may  
9 be fabricated on semiconductor substrate wafer 102 (exemplary embodiments are  
10 shown in Figs. 1A/1B, 4A/4B/4C, 5A/5B/5C, and 6A/6B/6C). Integrated waveguide 200  
11 comprises waveguide core 204 and upper and lower waveguide cladding layers  
12 206/208. Upper and lower waveguide cladding layers 206/208 may each include one or  
13 more layers adapted in any suitable way for providing substantial optical confinement of  
14 waveguide optical modes in vertical directions. Substantial optical confinement in  
15 vertical directions may be achieved in a variety of ways, including but not limited to:  
16 index contrast (between core 204 and cladding layers 206 and/or 208), single-layer  
17 and/or multi-layer reflection from layers 206 and/or 208, and so on. Upper and lower  
18 cladding layers 206/208 may be substantially identical, or may differ (in thickness,  
19 index, material(s), and/or structure) depending on the particular requirements for  
20 waveguide 200. Spatially selective material processing steps of any suitable type are  
21 employed for providing substantial optical confinement of waveguide optical modes in  
22 lateral directions. Substantial optical confinement in lateral directions may be achieved  
23 in a variety of ways, including but not limited to: index contrast between medial and  
24 lateral portions of layers 204, 206, and/or 208; physical and/or chemical modification of  
25 medial and/or lateral portions of layers 204, 206, and/or 208; removal of lateral portions  
26 of (i) an upper portion of layer 206, (ii) layer 206 and an upper portion of layer 204, (iii)  
27 layers 206 and 204 and an upper portion of layer 208, or (iv) all of layers 204, 206, and  
28 208; replacement of lateral layer portions thus removed with lower-index lateral cladding  
29 material; single-layer and/or multi-layer reflection from coatings applied to lateral  
30 surfaces of the end-coupled waveguide 200; surrounding (at least in part) portions of

1 the end-coupled waveguide 200 with lower-index media (including vacuum, air, inert  
2 gas, encapsulation media, and so forth); and other suitable means.

3 **[0048]** The accuracy and precision of spatially selective material processing  
4 techniques enable substantial spatial mode matching of device-supported and  
5 waveguide-supported optical modes, and enable sufficiently accurate alignment of  
6 optical waveguide 200 with respect to the device waveguide 100 in both vertical and  
7 horizontal directions. The required end-coupling efficiency (i.e., end-coupling efficiency  
8 at or above an operationally acceptable level) determines to what extent the device and  
9 waveguide optical modes must be spatially mode matched. The device waveguide 100  
10 and the end-coupled waveguide 200 may be designed to support optical modes that are  
11 substantially spatially mode matched to within the accuracy limits of the spatially  
12 selective material processing steps employed for their fabrication (typically on the order  
13 of 0.2  $\mu\text{m}$  or better horizontally and 0.1  $\mu\text{m}$  or better vertically for many such process  
14 steps). The accuracy required for relative lateral and vertical alignment is determined  
15 by the respective device and waveguide transverse mode sizes, and the operationally  
16 acceptable optical coupling level required for a particular use of the device and  
17 integrated waveguide. Alignment accuracy on the order of 0.1  $\mu\text{m}$  may be required for  
18 alignment of the device waveguide 100 and the integrated waveguide 200 under the  
19 most stringent circumstances (i.e., under operational conditions requiring near-unity  
20 end-coupling efficiencies), and such alignment accuracy is readily attained using  
21 spatially selective material processing techniques. Moreover, spatially selective  
22 material processing techniques may be employed for achieving the required alignment  
23 accuracy on a wafer scale for multiple semiconductor optical device waveguides 100  
24 and corresponding integrated end-coupled optical waveguides 200 on a common  
25 substrate wafer 102.

26 **[0049]** In an exemplary process for forming an integrated end-coupled optical  
27 waveguide (Fig. 7), a lower waveguide cladding layer 208 is first deposited (after  
28 forming waveguide 100 and end face 120). This typically results in deposition of the  
29 lower cladding material(s) also on the end face 120 (or on any coating layer(s) thereon)  
30 and on the top of at least an end portion of the device waveguide 100. Directional  
31 properties of the deposition process and the orientation of substrate 102 relative to the

1 deposition source determine the thickness of the lower cladding material deposited on  
2 the device end face 120 relative to the thickness of the lower waveguide cladding layer  
3 208. For example, the thicknesses may be substantially equal in thickness for a  
4 substantially conformal deposition process on a substrate oriented substantially  
5 perpendicularly relative to the deposition source, while the thicknesses may  
6 substantially differ for a highly directional deposition process. The thickness of the  
7 lower waveguide cladding layer 208 is chosen to achieve substantial vertical alignment,  
8 within operationally acceptable tolerances, between a device-supported optical mode  
9 and a corresponding waveguide-supported optical mode (once fabrication of waveguide  
10 200 is complete). The thickness of lower waveguide cladding layer 208 therefore may  
11 or may not correspond to the thickness of lower device layer 108, depending on the  
12 structural details and optical design of device waveguide 100 and integrated waveguide  
13 200.

14 **[0050]** After deposition of lower waveguide cladding layer 208, waveguide core 204  
15 may be deposited over layer 208. This typically results in deposition of the waveguide  
16 core material(s) also on the end face 120 and on the top of at least an end portion of the  
17 device waveguide 100 (over lower cladding material(s) already deposited). As  
18 described in the preceding paragraph, directional properties of the deposition process  
19 and the orientation of substrate 102 relative to the deposition source determine the  
20 thickness of the core material deposited on the device end face 120 relative to the  
21 thickness of the waveguide core layer 204. An upper waveguide cladding layer 206 is  
22 deposited over core 204. This typically results in deposition of the upper cladding  
23 material(s) also on the end face 120 and on the top of at least an end portion of the  
24 device waveguide 100 (over the lower cladding and core material(s) already deposited).  
25 As described in the preceding paragraph, directional properties of the deposition  
26 process and the orientation of substrate 102 relative to the deposition source determine  
27 the thickness of the upper cladding material deposited on the device end face 120  
28 relative to the thickness of the waveguide upper cladding layer 206. Upper waveguide  
29 cladding layer 206 need only be thick enough (or otherwise suitably adapted) for  
30 ensuring substantial optical confinement of waveguide optical modes from above.  
31 Portions of layers 208, 204, and/or 206 deposited on device waveguide end face 120

1 results on a proximal end segment 201 of integrated waveguide 200 that may lack  
2 substantially complete transverse optical confinement of an optical mode. Such a  
3 waveguide segment may result in diffractive optical loss, and may require structural  
4 adaptations of device waveguide 100 and/or integrated waveguide 200, and/or  
5 adaptations of spatially selective material processing procedures used to form the same  
6 (described further hereinbelow).

7 **[0051]** Spatially selective material processing is employed, at one or more stages  
8 during the deposition of layers 204, 206, and/or 208 for providing lateral optical  
9 confinement of waveguide optical modes as described hereinabove. Vertical and lateral  
10 dimensions, positions, and structural details of layers 204, 206, and/or 208 at and near  
11 the proximal end of waveguide 200 (i.e., the end-coupled end adjacent the optical  
12 device waveguide 100) are chosen so as to result in the required degree of transverse  
13 alignment and spatial mode matching, within operationally acceptable tolerances,  
14 between device and waveguide optical modes (once the waveguide fabrication is  
15 complete).

16 **[0052]** Variations on the generic structure of the semiconductor optical device  
17 waveguide 100 and integrated end-coupled optical waveguide 200 as described  
18 hereinabove, and variations on the generic methods for fabricating the same, are  
19 manifold, and choice of a particular structure and/or fabrication method depends on the  
20 particular structural and/or performance requirements, design constraints, cost and/or  
21 other manufacturing restrictions, and so forth that may apply for a given semiconductor  
22 optical device and/or its fabrication and/or its use. A sampling of various exemplary  
23 semiconductor optical devices, uses thereof, and corresponding variations in structure  
24 and/or fabrication methods thereof, is set forth hereinbelow. Variations of structure  
25 and/or fabrication of a semiconductor optical device and integrated end-coupled optical  
26 waveguide not explicitly set forth hereinbelow may nevertheless fall within the scope of  
27 the present disclosure and/or the appended claims.

28 **[0053]** Various spatially selective material processing procedures used to form end  
29 face 120 may not typically yield a substantially flat substantially vertical end face, but  
30 may instead leave a protrusion or "foot" 120a at the base of the end face, as shown

1 schematically in Fig. 31. In some instances a trench may instead be formed in the  
2 substrate near the base of end face 120, or a combination of a trench and a foot may be  
3 formed. The particular size and/or shape of the foot and/or trench depends on the  
4 particular spatially selective material processing technique(s), and the particular  
5 parameters thereof, employed for forming the end face. Such dependencies of the  
6 size/shape of a foot/trench may be readily characterized and reproduced by those  
7 skilled in the art of spatially selective material processing. The presence of such a foot  
8 and/or trench at or near the base of the end face 120 may complicate the accurate  
9 deposition of layers for forming integrated end-coupled waveguide 200, particularly at  
10 the proximal end thereof. As seen in the bottom portion of Fig. 31, the proximal portion  
11 of waveguide core 204 may not line up properly with device waveguide 100 when a foot  
12 120a is present.

13 **[0054]** Various spatially selective material processing procedures may not typically  
14 yield deposited layers of substantially uniform thickness near end face 120. Many such  
15 procedures yield material layers that decrease in thickness toward the base of the end  
16 face, as shown schematically in Fig. 32. The decrease in layer thickness may become  
17 more pronounced as the spatially selective material processing deviates from  
18 substantial conformality. The particular size and/or shape of the decreasing layer  
19 thickness depends on the particular spatially selective material processing technique(s),  
20 and the particular parameters thereof, employed for forming the layer. Such  
21 dependencies of the decreasing layer thickness may be readily characterized and  
22 reproduced by those skilled in the art of spatially selective material processing. A lower  
23 cladding layer 208 that decreases in thickness near end face 120 may complicate the  
24 accurate deposition of subsequent layers for forming integrated end-coupled waveguide  
25 200, particularly the proximal end thereof. As seen in the bottom portion of Fig. 32, the  
26 proximal portion of waveguide core 204 may not line up properly with device waveguide  
27 100 if the waveguide layer thicknesses decrease near the end face 120.

28 **[0055]** These complications in a fabrication procedure for integrated end-coupled  
29 waveguide 200 may be suitably adapted to mitigate the effects of one another. A  
30 suitably configured foot 120a may be intentionally formed and shaped at the base of the  
31 end face 120 of device waveguide 100, so as to substantially compensate for non-

1 uniform layer deposition near the end face. Conversely, a deposition process may be  
2 intentionally contrived to yield a non-uniform layer thickness near end face 120, so as to  
3 substantially compensate for the size and shape of the foot 120a. Alternatively, the size  
4 and shape of a foot 120a at the base of end face 120 and the non-uniformity of the  
5 deposition process may be optimized together so as to substantially compensate for  
6 each other. Fig. 33 illustrates such an adapted procedure, in which the upper surface of  
7 lower waveguide cladding layer 208 is substantially flat as a result of a) the presence of  
8 foot 120a at the base of the end face 120 of the device waveguide 100, and b)  
9 decreasing deposited layer thickness of lower waveguide cladding layer 208 near the  
10 end face. If the size and shape of the foot 120a are properly chosen and formed, based  
11 on the behavior of the deposition process used to form layer 208 and the desired  
12 thickness of layer 208, the upper surface of layer 208 may be made substantially flat up  
13 to a point closer to the end face than if the entire end face were substantially flat and  
14 vertical. Conversely, if the deposition process for end-coupled waveguide 200 is  
15 suitably contrived, based on the size and shape of the foot 120a and the desired  
16 thickness of layer 208, the upper surface of layer 208 may be made substantially flat up  
17 to a point closer to the end face than if the layer deposition were substantially uniform.  
18 The size and shape of foot 120a and the layer deposition process may be optimized  
19 together for achieving a substantially flat upper surface of layer 208. Such  
20 compensation facilitates fabrication of integrated end-coupled waveguide 200 for  
21 achieving operationally acceptable levels of spatial mode-matching, optical power end-  
22 transfer efficiency, and so forth.

23 **[0056]** Fig. 34 illustrates schematically the formation of lower waveguide cladding layer  
24 208 over foot 120a of the device waveguide end face 120. Early in the deposition  
25 (before the optimum layer thickness is reached; the first stage of the deposition process  
26 shown in Fig. 34), the presence of foot 120a dominates over the thinner deposition near  
27 the end face, and the upper surface of layer 208 curves upward near the end face. Late  
28 in the deposition process (beyond the optimum layer thickness; the last stage of the  
29 deposition process shown in Fig. 34), the non-uniformity of the deposition process near  
30 the end face 120 dominates over the presence of foot 120a, and the upper surface of  
31 layer 208 curves downward near the end face. At some intermediate point (i.e., the

1 optimum layer thickness; the middle stage of the deposition process shown in Fig. 34),  
2 the upper surface of layer 208 is substantially flat as it approaches the end face 120.  
3 The size and shape of foot 120a may be suitably formed, the deposition of layer 208  
4 may be suitably adapted, and/or the device waveguide 100 may be suitably formed, so  
5 that the optimum thickness for layer 208 (i.e., the thickness that yields a substantially  
6 flat upper surface thereof) corresponds to the desired thickness for layer 208 to  
7 substantially align the integrated end-coupled waveguide 200 (once it is formed) with  
8 device waveguide 100.

9 **[0057]** Among numerous exemplary types of spatially selective material processing  
10 techniques that may be employed within the scope of the present disclosure for forming  
11 end face 120 are dry etching techniques, such as ion etching, reactive ion etching, and  
12 so forth. In these techniques, an edge of an etch mask typically defines end face 120,  
13 and bombardment by ions removes material from the adjacent unmasked area to form  
14 the end face. These techniques typically do not yield a substantially perpendicular  
15 intersection between the substantially vertical end face and a substantially flat adjacent  
16 portion of the substrate surface, but may instead may form a trench near the base of the  
17 end face, a protruding foot near the base of the end face, or both (as described  
18 hereinabove). The particular size and/or shape of the trench and/or foot is determined  
19 by the particular processing conditions and the particular etching tools employed, and  
20 these may be readily characterized and reproduced by those skilled in the art.  
21 Examples of processing conditions that may be varied and/or calibrated for controlling  
22 the formation by etching of end face 120 and foot 120a may include one or more of, but  
23 are not limited to: reactive and/or non-reactive ion species (identity of single ion species;  
24 identity and composition of ion mixtures); ion density(ies); ion energy(ies); gas flow  
25 rate(s); chamber pressure; substrate temperature; geometry of ion source(s) and target  
26 substrate; and so forth. In addition to these exemplary etching processes, other  
27 suitable types of spatially selective material processing, and varying processing  
28 conditions therefor, may be employed for forming end face 120 and foot 120a and for  
29 controlling the size and/or shape thereof, while remaining within the scope of the  
30 present disclosure.

1 **[0058]** Among numerous exemplary types of spatially selective material processing  
2 techniques, that may be employed within the scope of the present disclosure for forming  
3 layers 204/206/208 of waveguide 200, are various material deposition techniques, such  
4 as vacuum evaporation, sputter deposition (reactive and non-reactive), molecular beam  
5 epitaxy, chemical vapor deposition, plasma-enhanced chemical vapor deposition,  
6 photochemical vapor deposition, laser chemical vapor deposition, metal-organic  
7 chemical vapor deposition, and so forth. The particular set of deposition conditions  
8 employed for these techniques may be varied and/or calibrated for controlling the  
9 conformality of the deposition (or deviation therefrom). Many of these deposition  
10 techniques typically produce layers of decreasing thickness near the base of a vertical  
11 end face (as described hereinabove), even when optimized for maximal conformality.  
12 The degree of layer non-uniformity, and the distances from the end face over which the  
13 layer thickness may vary, are typically dependent on the particular deposition technique  
14 used and processing conditions employed therefor. These may be readily  
15 characterized and reproduced by those skilled in the art. Examples of processing  
16 conditions that may be varied for controlling the formation of end face 120 and foot 120a  
17 include one or more of, but are not limited to: chemical precursor species employed  
18 (identity of single precursor species; identity and composition of precursor mixtures);  
19 gas flow rate(s); chamber pressure; deposition substrate temperature; RF power(s)  
20 and/or frequency(ies) for plasma-enhanced processes; sputtering ion source(s);  
21 sputtering ion energy(ies); sputtering target composition; sputtering target temperature;  
22 reactive ion density(ies) and/or energy(ies); geometry of deposition substrate,  
23 deposition source(s), sputtering target, and/or sputtering source(s); and so forth. In  
24 addition to these deposition processes, other suitable types of spatially selective  
25 material processing, and varying processing conditions therefor, may be employed for  
26 forming layers 204, 206, and/or 208, and for controlling the thickness variation(s)  
27 thereof, while remaining within the scope of the present disclosure.

28 **[0059]** A given implementation of the compensation scheme described in the  
29 preceding paragraphs is typically dependent on the particular spatially selective material  
30 processing techniques employed, the processing conditions employed for those  
31 techniques, and may even vary among individual fabrication apparatus used for those

1 techniques. Accordingly, implementation of the compensation scheme by those skilled  
2 in the art of spatially selective material processing may typically involve a significant  
3 degree of characterization of the processes used, the processing conditions thereof,  
4 and the size and shape of structures formed thereby. For example, an etching process  
5 used to form end face 120 and foot 120a might be performed on test structures using a  
6 given apparatus under ranges of etching conditions, and the resulting structures  
7 examined to determine which set of conditions produced the most suitable size and  
8 shape for foot 120a. That set of conditions could then be used for producing end faces  
9 each having a foot of the selected size and shape. The characterization process may  
10 typically be repeated for another apparatus (even one performing nominally the same  
11 etching procedure as the first), or even for the first apparatus after a cleaning, overhaul,  
12 upgrade, or other modification. In an analogous example, a deposition process used for  
13 forming one or more of layers 204/206/208 might be performed on test structures using  
14 a given apparatus under ranges of deposition conditions, and the resulting structures  
15 examined to determine which set of conditions produced the most suitable layer  
16 thickness variation. That set of conditions could then be used for producing layers  
17 having the selected thickness variation. As with the etching of the end face 120, the  
18 characterization may typically be repeated for a different apparatus, or for the first  
19 apparatus after any significant change or maintenance thereof. In another example, the  
20 preceding characterization processes may be combined, with various sizes and shapes  
21 for foot 120a being subjected to varying deposition conditions, and selecting the  
22 combination of etching and deposition conditions yielding the most suitable overall  
23 structure for end face 120, foot 120a, and layers 204, 206, and/or 208. Any such  
24 characterization of spatially selective material processing techniques, and conditions  
25 therefor, for yielding suitable structures shall fall within the scope of the present  
26 disclosure.

27 **[0060]** While the foregoing exemplary procedures have shown adaptations for yielding  
28 a substantially flat upper surface for lower waveguide cladding layer 208, it may be  
29 desirable in some circumstances to instead optimize the overall fabrication procedure  
30 for waveguide 200 to yield a substantially flat upper surface for some other layer or  
31 structure, such as waveguide core 204 or upper waveguide cladding layer 206.

1 Alternatively, it may be desirable in other circumstances to form one or more layer  
2 surfaces that are not substantially flat, but are curved to achieve some desired design  
3 characteristic and/or optical performance. The size and/or shape of foot 120a, and/or  
4 the deposition of one or more of layers 204/206/208, may be adapted in any suitable  
5 manner to yield a desired layer configuration for waveguide 200 while remaining within  
6 the scope of the present disclosure. It should be noted that the compensation scheme  
7 described in the preceding paragraphs (a foot on the etched facet and non-uniform layer  
8 deposition compensating for one another to form a substantially flat layer surface) may  
9 be combined with various other structures and/or fabrication techniques described  
10 herein.

11 **[0061]** A specific exemplary embodiment of a semiconductor optical device and  
12 integrated end-coupled optical waveguide is illustrated in Fig. 8. A semiconductor laser  
13 is shown comprising a planar laser waveguide 300 on semiconductor substrate 302, the  
14 planar laser waveguide 300 comprising upper and lower laser confinement layers 306  
15 and 308, respectively, surrounding laser active layer 304. Laser confinement layers  
16 306/308 may often provide both optical confinement of semiconductor laser optical  
17 modes as well as charge carrier confinement for localizing optical gain within the  
18 semiconductor laser. Semiconductor laser 300 may typically comprise a III-V  
19 semiconductor laser, with active laser layer 304 comprising a III-V semiconductor multi-  
20 quantum well. Many other suitable semiconductor materials and/or structures may be  
21 alternatively employed for layers 304, 306, and/or 308. After spatially selective material  
22 processing to form laser planar waveguide 300 with end face 320, and application of  
23 any optical coating(s) on end face 320 (if needed or desired; not shown in Fig. 8), an  
24 end-coupled integrated planar optical waveguide 330 may be formed comprising a  
25 silicon nitride core 334 and silica-based cladding layers 336/338. Other waveguide core  
26 and/or cladding materials may be alternatively employed for forming waveguide 330.  
27 The thickness of lower waveguide cladding layer 338 may be chosen so as to  
28 substantially align (within operationally acceptable tolerances) core 334 with active laser  
29 layer 304. Vertical and lateral dimensions of core 334 near the proximal end of  
30 waveguide 330 are chosen to achieve the required degree of spatial mode matching  
31 (within operationally acceptable tolerances). As an example, a transverse mode

1 supported by a III-V semiconductor laser gain medium may be about 1  $\mu\text{m}$  high by  
2 about 2-3  $\mu\text{m}$  wide. A silicon nitride core about 50-200 nm thick by about 2-3  $\mu\text{m}$  wide  
3 within silica-based cladding would support a transverse mode substantially spatial-mode  
4 matched with the mode of the semiconductor gain medium.

5 **[0062]** Semiconductor laser waveguide 300 may include at its other end a second end  
6 face 310. End face 310 of the semiconductor laser waveguide 300 may be formed  
7 using spatially selective material processing steps on a wafer scale, and may be formed  
8 concurrently or sequentially relative to end face 320. Alternatively, laser end face 310  
9 may be formed by cleaving or otherwise dividing the semiconductor substrate wafer  
10 (into bars or into individual device chips; not shown in Fig. 8). However it is formed, end  
11 face 310 may serve as a laser resonator end mirror. In order to function as a laser end  
12 mirror, the reflectivity of end face 310 must be sufficiently large at the laser wavelength  
13 for enabling the semiconductor laser to reach threshold and achieve laser oscillation.  
14 Index contrast between laser waveguide 300 and its surroundings may provide  
15 sufficient reflectivity, or end face 310 may be provided with a coating sufficiently  
16 reflective for the laser wavelength. Transmission at the lasing wavelength results in  
17 laser output through end face 310 upon laser oscillation. This may be a primary or a  
18 secondary output of the semiconductor laser; if the secondary output, it may simply  
19 dissipate or it may be used for monitoring the operation of the semiconductor laser or  
20 for some other purpose. If the reflectivity of end face 310 is sufficiently large, laser  
21 output therethrough may be substantially eliminated. A reflective coating for end face  
22 310 may be applied to all of the multiple semiconductor lasers formed on a common  
23 semiconductor substrate wafer 302 (wafer-scale coating), if end face 310 is also formed  
24 by wafer scale spatially selective material processing. Alternatively, any reflective  
25 coating on end face 310 (however it is formed) may be applied to rows of multiple  
26 semiconductor lasers after dividing the common substrate wafer into strips each having  
27 a single row of lasers thereon (i.e., at the "bar" level, as opposed to the "wafer" level), or  
28 may be applied to individual semiconductor lasers after dividing the common substrate  
29 wafer into individual laser chips.

30 **[0063]** Prior to fabrication of end-coupled waveguide 330, end face 320 of  
31 semiconductor laser waveguide 300 may be coated in any suitable manner to achieve

1 desired laser output and/or performance characteristics (coating layer(s) 322 shown in  
2 Figs. 9A/9B/9C/9D). A partially reflective coating (at the laser wavelength) may be  
3 applied, so that end face 320 may serve as an output coupling mirror of a  
4 semiconductor laser resonator while transmitting laser output therethrough. End face  
5 310 serves as the other laser resonator mirror, and the laser waveguide 300 comprises  
6 the entire semiconductor laser optical resonator. End-coupled waveguide 330 in this  
7 instance serves to receive the output of the semiconductor laser transmitted through  
8 end face 320 (either a primary or a secondary output of the laser), which propagates  
9 from the laser 300 through the waveguide 330 to its intended destination (described  
10 further hereinbelow). Any suitably reflective coating may be employed on end face 320.  
11 A series of alternating quarter-wave coating layers may be employed as a reflective  
12 coating for end face 320, for example. Other reflective coatings may be equivalently  
13 employed. Application of coating layers during wafer scale processing may typically  
14 also result in deposition of coating material on adjacent areas of the semiconductor  
15 substrate wafer 302 and/or the top of the laser waveguide 300 (Fig. 9A). One or more  
16 of these (presumably) unwanted areas of coating material may be removed prior to  
17 deposition of lower waveguide cladding layer 338 (using additional spatially selective  
18 material processing steps; Fig. 9B), or may be left in place (the reflective coating area  
19 on the substrate 302 therefore forming a portion of lower waveguide cladding layer 338  
20 near end face 320 upon fabrication of waveguide 330; Fig. 9C or 9D).

21 **[0064]** Instead of forming a substantially complete laser optical resonator (including  
22 laser resonator end mirrors on both of end faces 310 and 320), the laser waveguide 300  
23 may instead form only a portion of the semiconductor laser optical resonator. The  
24 integrated end-coupled planar waveguide 330 may be configured so as to also form a  
25 portion of the laser optical resonator. End face 310 may function as one laser resonator  
26 end mirror, while a portion of the integrated end-coupled waveguide 330 is suitably  
27 adapted to serve as the other laser resonator end mirror. One such adaptation may  
28 include a partially or totally reflecting distal end face 332 of waveguide 330 (Fig. 10).  
29 Another such adaptation may include a waveguide grating 340 provided along at least a  
30 portion of waveguide 330 (Fig. 11). Such a waveguide grating provides wavelength  
31 selective reflectivity for the semiconductor laser resonator mirror, thereby stabilizing the

1 output wavelength of the laser. Additional optical functionality for the semiconductor  
2 laser may be incorporated into waveguide 330, including but not limited to: modification,  
3 selection, suppression, control, and/or modulation of laser transverse modes;  
4 modification, control, and/or modulation of laser longitudinal mode frequencies;  
5 modification, control, and/or modulation of optical loss within the laser resonator; and so  
6 forth.

7 **[0065]** For laser embodiments in which waveguide 330 forms a portion of the laser  
8 resonator, end face 320 may be provided with an anti-reflection coating 322 (prior to  
9 fabrication of waveguide 330). An anti-reflection coating may serve to reduce or  
10 eliminate laser oscillation arising from reflection at end face 320. Such an anti-reflection  
11 coating may simply comprise a single quarter-wave- thickness layer of material having  
12 an index intermediate between that of the laser waveguide 300 and the integrated  
13 waveguide 330 (a silicon nitride  $\lambda/4$  layer between a III-V semiconductor laser  
14 waveguide 300 and a silica-clad, silicon-nitride-core waveguide 330, for example).  
15 More complex anti-reflection coatings may be equivalently employed. As with the  
16 deposition of reflective coating layers described hereinabove, anti-reflection coating  
17 material is typically deposited on adjacent areas of the substrate 302 and the top of the  
18 laser waveguide 300 along with end face 320 (as in Fig. 9A). The coating material may  
19 be removed from substrate 302 prior to deposition of lower waveguide cladding layer  
20 338 (using additional spatially selective material processing steps; Fig. 9B), or may be  
21 left in place and therefore form a portion of lower cladding layer 338 near end face 320  
22 (upon fabrication of waveguide 330; Fig. 9C or 9D). For other laser embodiments in  
23 which waveguide 330 forms a portion of the laser resonator, some degree of reflection  
24 from end face 320, in addition to laser end mirror reflectivity provided by waveguide  
25 330, may impart desirable laser output and/or operating characteristics. Such  
26 reflectivity may be simply provided by index contrast between laser waveguide 300 and  
27 integrated end-coupled waveguide 330, or may be provided in a more specifically  
28 designed manner by application of appropriate coating layer(s) 322 to end face 320  
29 (prior to fabrication of waveguide 330). As with the deposition of reflective and anti-  
30 reflective coating layers described hereinabove, such coating layer(s) are typically  
31 deposited on adjacent areas of the substrate 302 and the top of the laser waveguide

1 300 along with end face 320 (Fig. 9A). The coating material may be removed from  
2 substrate 302 prior to deposition of lower waveguide cladding layer 338 (using  
3 additional spatially selective material processing steps; Fig. 9B), or may be left in place  
4 and therefore form a portion of lower cladding layer 338 near end face 320 (upon  
5 fabrication of waveguide 330; Fig. 9C or 9D).

6 **[0066]** The presence of lower cladding material between the proximal end of core 204  
7 and the end face of device waveguide 100, and core material extending upward from  
8 the proximal end of the core (as in Fig. 7), may be suitably adapted to modify the overall  
9 effective reflectivity between the device waveguide and integrated waveguide 200. The  
10 depth and conformality of the deposition process for lower cladding 208 may be  
11 adjusted to provide a desired thickness for the lower cladding material between the  
12 device end face and the upwardly extending core material. If reduced reflectivity at the  
13 end face is desired, this desired thickness may be chosen so as to result in partial  
14 destructive interference between light reflected from the end face and light reflected  
15 from the upwardly extending core material. Conversely, if enhanced reflectivity is  
16 desired, the desired lower cladding material thickness may be chosen so as to result in  
17 partial constructive interference between the two reflections. In either case the  
18 interference typically would be only partial, since the reflected amplitudes may differ,  
19 and since the upwardly extending core material would not reflect light entering/exiting  
20 the lower portion of the device end face. Choosing the cladding material thickness for  
21 either minimizing or maximizing the effective reflectivity of the end face and core  
22 material also serves to reduce the variation of effective reflectivity with wavelength.

23 **[0067]** An integrated end-coupled waveguide may be provided for a semiconductor  
24 laser or other semiconductor optical device to serve a variety of purposes. For  
25 example, mode sizes within the typically high-index laser waveguide 300 are typically  
26 quite small (in at least the vertical dimension). End-coupled solutions (i.e., those not  
27 employing an integrated waveguide as disclosed herein) generally impose stringent  
28 tolerances (on the order of 0.1  $\mu\text{m}$ ) for accuracy and stability of relative alignment of the  
29 laser, transmission component, and any required intervening focusing optics, or else  
30 achieve low coupling efficiencies (less than 20% or even 10% in some cases). Side-  
31 coupled solutions (also referred to as transverse-transfer or evanescent optical coupling

1 or directional coupling) between waveguides of widely differing modal indices (around 3  
2 for a III-V semiconductor laser, around 1.5 for silica based optical waveguides and  
3 fibers) may be problematic due to modal index mismatch. An integrated end-coupled  
4 waveguide may mitigate these various difficulties and facilitate transfer of laser output  
5 power from a semiconductor laser into an optical transmission system.

6 **[0068]** For end-coupling between a semiconductor laser and an optical transmission  
7 component (Figs. 12A/12B and 13A/13B), the integrated end-coupled waveguide 330  
8 may be adapted at its proximal end to be substantially spatially mode matched with  
9 laser waveguide 300 (as described hereinabove), and adapted along its length for  
10 transverse expansion of the optical mode. Alignment between laser waveguide 300 and  
11 integrated waveguide 330 is pre-determined by the spatially selective material  
12 processing techniques employed for fabricating waveguide 330 (and is therefore  
13 typically well within operationally acceptable limits), while integration of waveguide 330  
14 onto a common substrate 302 with laser waveguide 300 substantially eliminates issues  
15 of position stability therebetween. Waveguide 330 may be adapted along at least a  
16 portion of its length for transverse optical mode expansion, so that the laser output  
17 emerges from a distal end face 332 of waveguide 330 with decreased divergence and  
18 increased transverse extent relative to the optical mode at the proximal end of  
19 waveguide 330 (i.e., at end face 320 of semiconductor laser waveguide 300).  
20 Alignment tolerances and position stability requirements for end-coupling the  
21 semiconductor laser (via waveguide 330) to an optical transmission component, such as  
22 an optical fiber or optical waveguide, may therefore be considerably relaxed by suitable  
23 adaptation of waveguide 330, relative to tolerances currently required for achieving  
24 comparable coupling efficiency for a laser without a mode-expanding integrated  
25 waveguide.

26 **[0069]** An exemplary semiconductor laser as shown in Figs. 12A/12B and 13A/13B  
27 may include a III-V semiconductor laser waveguide 300 and an integrated waveguide  
28 330 having a silicon nitride core 334 within or on a silica-based secondary core 334' and  
29 silica or silica-based cladding 336/338. A typical transverse mode size at end face 320  
30 may range between about 1  $\mu\text{m}$  and about 4  $\mu\text{m}$  wide and between about 0.5  $\mu\text{m}$  high  
31 and about 2  $\mu\text{m}$  high. The transverse dimensions of silicon nitride core 334 at the

1 proximal end of integrated waveguide 330 may be designed and fabricated to achieve  
2 an operationally acceptable degree of spatial mode matching between laser waveguide  
3 300 and integrated waveguide 330. Silicon nitride core 334 may therefore range  
4 between about 50 nm and about 200 nm thick, typically between about 80 nm and  
5 about 120 nm thick, often about 100 nm thick, and may therefore range between about  
6 1  $\mu\text{m}$  wide and about 4  $\mu\text{m}$  wide, typically between about 1.5  $\mu\text{m}$  wide and about 3  $\mu\text{m}$   
7 wide, often about 2  $\mu\text{m}$  wide. At least one transverse dimension of the silicon nitride  
8 core 334 (often the width) gradually decreases with the distance from end face 320  
9 along waveguide 330 and the core eventually terminates. The transverse dimensions of  
10 secondary core 334' may be designed and fabricated to achieve an operationally  
11 acceptable degree of spatial mode matching at the distal end of waveguide 330 with  
12 fiber 401 (Figs. 12A/12B) or waveguide 404 (on substrate 402; Figs. 13A/13B; cores  
13 334/334' not shown). The transverse dimensions of secondary core 334' may remain  
14 substantially constant along the length of waveguide 330. As the silicon nitride core  
15 gradually tapers away, the transverse mode size supported by waveguide 330 gradually  
16 increases from about 1  $\mu\text{m}$  high by about 2  $\mu\text{m}$  wide (for example), supported by the  
17 silicon nitride core 334 at the proximal end of waveguide 330, to about 2-3  $\mu\text{m}$  high by  
18 about 4-6  $\mu\text{m}$  wide or larger, supported by suitably-sized secondary core 334' at the  
19 distal end of waveguide 330 (a silica-based core about 0.5-1.5  $\mu\text{m}$  high and about 4-8  
20  $\mu\text{m}$  wide within silica-based cladding, for example). Transverse mode sizes in this  
21 range may be more readily end-coupled to an optical fiber 401 (shown positioned in a  
22 V-groove 301 on substrate 302 in Figs 12A/12B), planar optical waveguide 404 on a  
23 waveguide substrate 402 (shown "flip-chip" mounted in Figs. 13A/13B; alignment/  
24 support structures not shown), or other optical transmission component with relaxed  
25 alignment tolerances and/or greater coupling efficiency, as compared to a  
26 semiconductor laser lacking such a mode expander.

27 **[0070]** Such mode expansion functionality for end-coupling may be provided by  
28 waveguide 330 regardless of whether it forms part of the semiconductor laser resonator  
29 or not. If integrated waveguide 330 does form part of the semiconductor laser  
30 resonator, transverse mode expansion may be provided along a portion of waveguide  
31 330 within the semiconductor laser resonator, along a portion of waveguide 330 outside

1 the semiconductor laser resonator, or along portions both within and outside the  
2 semiconductor laser resonator. Distal end face 350 of waveguide 330 may be provided  
3 with an anti-reflection coating, if needed or desired, whether or not waveguide 330  
4 forms a portion of the semiconductor laser resonator. Alternatively, if waveguide 330  
5 does form a portion of the semiconductor laser resonator, and if resonator end-mirror  
6 reflectivity is not otherwise provided, distal end face 350 of waveguide 330 may be  
7 provided with a partially-reflective coating (at the laser wavelength), and may therefore  
8 serve as a semiconductor laser resonator output coupling mirror. A coating applied to  
9 distal end face 350 may be applied on a wafer scale to multiple waveguides 330  
10 simultaneously (in a manner similar to coatings applied to end faces 310 and/or 320 on  
11 a wafer scale, as described hereinabove). Alternatively, coatings may be applied to end  
12 face 350 at the "bar" level or at the individual laser "chip" level.

13 **[0071]** Transverse mode expansion along waveguide 330 may result in leakage of a  
14 fraction of the transmitted optical power into substrate 302, particularly from low-index  
15 materials of waveguide 330 into a high-index semiconductor substrate 302. Such  
16 optical loss may be kept within operationally acceptable levels in a variety of ways within  
17 the scope of the present disclosure. It may be possible to provide a sufficiently thick  
18 lower cladding layer for waveguide 330 so that optical leakage therefrom into substrate  
19 302 is sufficiently reduced or substantially eliminated. It may be possible to reduce the  
20 overall length of beam-expanded portion of waveguide 330 so as to reduce the total  
21 optical power lost into the substrate. Additional measures may be implemented for  
22 reducing the degree of optical power loss due to substrate leakage.

23 **[0072]** A reflective layer (metallic, multilayer, or other; described further hereinbelow)  
24 may be deposited on substrate 302 prior to deposition of the lower cladding layer 338.  
25 Optical power reaching the reflective layer is thereby substantially prevented from  
26 leaking into substrate 302. In some instances, instead of employing a reflective film, it  
27 may be possible to rely on reflection (at high or grazing angles of incidence) at the lower  
28 cladding/substrate interface to at least reduce the amount of optical power leakage into  
29 a higher-index substrate 302 (so-called "anti-guiding"). A two-level, two-core  
30 configuration (not shown) may be employed for waveguide 330, in which a proximal end  
31 portion of waveguide 330 and a lower proximal lower core thereof are adapted for end-

1 coupling with a semiconductor laser 300, while a distal end portion of waveguide 330  
2 and an upper distal core thereof are adapted for end-coupling to an optical fiber or to an  
3 other planar waveguide. Along an intermediate portion of the waveguide 300, both  
4 lower and upper cores are present, and are adapted for transverse-transfer or optical  
5 power therebetween (i.e., optical transverse-coupling, side-coupling, or directional  
6 coupling). The transverse transfer may be substantially modal-index-matched mode-  
7 interference transverse-coupling, or may be substantially adiabatic transverse-coupling.  
8 The distal core may be suitably adapted for providing the desired degree of beam  
9 expansion, presumably with less leakage of optical power into substrate 302 due to the  
10 thicker lower cladding layer. Stability of such a two-level, two-core arrangement is  
11 ensured by the monolithic formation of the two cores within a common waveguide.  
12 Other adaptations and/or configurations may be equivalently employed for reducing  
13 leakage of optical power from an integrated waveguide into an underlying  
14 semiconductor device substrate while remaining within the scope of the present  
15 disclosure.

16 **[0073]** For side-coupling between a semiconductor laser and an optical transmission  
17 component, the integrated end-coupled waveguide 330 may be adapted at its proximal  
18 end to be substantially spatially mode matched with laser waveguide 300 (as described  
19 hereinabove), and suitably adapted along at least a portion of its length for facilitating  
20 transverse-transfer of optical power (as taught in U.S. Patent Application Pub. No.  
21 2003/0081902). It is typically the case that adaptations required for efficient transverse-  
22 transfer of optical power may be more readily implemented for integrated waveguide  
23 330 than for laser waveguide 300. For example, use of silica-based material(s) for  
24 fabricating waveguide 330 yields modal indices within waveguide 330 nearly matched to  
25 a corresponding modal index of a side-coupled silica-based optical transmission  
26 component, such as an optical fiber taper segment 501 (Figs. 14A/14B), a silica-based  
27 planar waveguide 504 on a substrate 502 (laser shown "flip-chip" mounted in Figs.  
28 15A/15B; alignment/support structures not shown), or other low-index transmission  
29 component. Modal-index-matched (equivalently, mode-interference-coupled)  
30 transverse-transfer may therefore be more readily achieved than between such low-  
31 index optical transmission components and the III-V laser waveguide 300. Alternatively,

1 a dispersion-engineered multi-layer reflector waveguide structure may be employed for  
2 waveguide 330, enabling modal index matching to low-index optical transmission  
3 components from III-V waveguide material. Incorporation of electro-optic, electro-  
4 absorptive, and/or non-linear optical materials into waveguide 330 may enable  
5 modification, control, and/or modulation of modal index matching (and therefore also  
6 transverse optical power transfer) between integrated end-coupled waveguide 330 and  
7 a side-coupled optical transmission component. In other exemplary embodiments,  
8 integrated waveguide 330 and/or the optical transmission component may be adapted  
9 for enabling substantially adiabatic transverse-transfer (Figs. 14A/14B and 15A/15B).  
10 The variation in optical properties along the length of waveguide 330 for enabling  
11 adiabatic transverse-transfer may be more readily implemented on waveguide 330 than  
12 directly on laser waveguide 300.

13 **[0074]** If waveguide 330 forms a portion of the semiconductor laser resonator, then the  
14 portion of waveguide 330 adapted for transverse-coupling (modal-index-matched or  
15 adiabatic) may be positioned outside the semiconductor laser resonator (i.e., distal of  
16 the portion of waveguide 330 providing resonator end mirror reflectivity). Alternatively, a  
17 portion of the optical transmission component (typically a planar waveguide 504 as in  
18 Figs. 15A/15B) may also form a portion of the semiconductor resonator and provide  
19 resonator end mirror reflectivity, in which case the portions of waveguide 330 and the  
20 planar transmission waveguide 504 adapted for transverse-coupling would be within the  
21 semiconductor laser resonator. In this latter example the semiconductor laser would not  
22 operate until sufficiently large (i.e., sufficiently low-loss) transverse-transfer is  
23 established between waveguide 330 and the planar transmission waveguide 504.

24 **[0075]** In some exemplary embodiments of a semiconductor laser including an  
25 integrated end-coupled waveguide, the integrated waveguide 330 may be present for  
26 modifying, controlling, and/or modulating the output of the semiconductor laser, while  
27 the primary laser output exits the semiconductor laser through end face 310 of  
28 semiconductor laser waveguide 300. In such embodiments the adaptations described  
29 hereinabove for distal end-coupling (to a transmission optical component), mode  
30 expansion, side-coupling, modal index matching, or adiabatic side-coupling typically  
31 would not be necessary. Those adaptations necessary for enabling at least a portion of

1 waveguide 330 to form at least a portion of the semiconductor laser resonator and for  
2 modifying the laser output may be incorporated into waveguide 330, such adaptations  
3 including but not limited to: waveguide grating(s), reflective and/or anti-reflective  
4 coating(s), transverse mode selector(s) and/or suppressor(s), and so forth. In some of  
5 these embodiments a secondary laser output may exit the semiconductor laser via  
6 waveguide 330, which may simply dissipate or which may be used for monitoring the  
7 operation of the semiconductor laser or for some other purpose.

8 **[0076]** In some exemplary embodiments of a semiconductor laser including a first  
9 integrated end-coupled waveguide 330, a second integrated end-coupled waveguide  
10 370 may be formed on semiconductor laser substrate 302 and end-coupled to  
11 semiconductor laser waveguide 300 at end face 310 (Figs.16A/16B). Spatially selective  
12 material processing may be employed for forming end face 310 and fabricating  
13 integrated waveguide 370 in manners similar to those employed for forming end face  
14 320 and integrated waveguide 330, and end face 310 and/or integrated waveguide 370  
15 may include suitable adaptations thereof for providing various functionalities and/or  
16 capabilities similar to those described above for end face 320 and/or integrated  
17 waveguide 330. The spatially selective material processing steps employed for forming  
18 laser waveguide 300, end faces 310 and 320, and waveguide 330 and 370, may be  
19 concurrent or sequential, and may be performed on a wafer scale for simultaneous  
20 fabrication of multiple sets of waveguides 300/330/370. In embodiments including  
21 integrated end-coupled waveguides at both ends of the semiconductor laser waveguide  
22 300, the various adaptations, functionalities, and/or capabilities that may be provided for  
23 and/or by such waveguides may be divided between the two waveguides 330 and 370  
24 in any suitable manner.

25 **[0077]** Integrated end-coupled waveguide(s) and adaptations thereof as described  
26 hereinabove for semiconductor lasers may be similarly implemented for a wide array of  
27 other active and/or passive semiconductor optical device types. Some of these devices  
28 may be single-port devices (including but not limited to photodetectors, receivers,  
29 single-output lasers, and so on; configured similar to the embodiment of Fig. 8), while  
30 others may be multi-port devices (including but not limited to multiple-output lasers,  
31 amplifiers, modulators, filters, splitters/combiners, add/drop filters, slicer/interleavers,

1 phase shifters, and so on; configured similar to Figs. 16A/16B). For any single- or multi-  
2 port semiconductor optical devices, one or more or all input/output ports may be  
3 provided with an integrated end-coupled waveguide as described hereinabove. For  
4 each such input/output port, a suitable array of adaptations, functionalities, and/or  
5 capabilities may be provided for/by the corresponding device waveguide end face and  
6 integrated end-coupled waveguide (as described in detail hereinabove for  
7 semiconductor lasers).

8 **[0078]** Fabrication of an integrated end-coupled waveguide on a device substrate  
9 along with semiconductor optical device waveguide using wafer scale spatially selective  
10 material processing techniques may require additional adaptations of the end face of  
11 the semiconductor device waveguide and/or the integrated waveguide, and may also  
12 require additional fabrication steps. For minimizing end-coupling optical loss due to  
13 diffraction, for example, transverse (vertical and lateral) optical confinement of device  
14 and waveguide modes should be substantially contiguous across the waveguide end  
15 faces, as shown in Figs. 1A/1B, where a semiconductor device ridge waveguide 100  
16 and ridge end-coupled waveguide 200 are shown integrated on semiconductor device  
17 substrate 102. However, various fabrication schemes for forming semiconductor device  
18 waveguide 100 and end face 120 thereof result in an end segment of the device  
19 waveguide that lacks complete transverse confinement. An examples is illustrated in  
20 Figs. 2C. Some fabrication schemes for forming integrated end-coupled waveguide 200  
21 result in waveguide material(s) deposited on end face 120, resulting in a proximal end  
22 segment 201 of waveguide 200 that lacks substantially complete transverse  
23 confinement (as in Fig. 7, for example). Elimination of either or both of these  
24 unconfined waveguide segments requires additional spatially selective material  
25 processing steps, adding to the cost and complexity of the manufacturing process. The  
26 diffraction loss induced by a gap in transverse confinement maybe tolerable in some  
27 device applications, but not in others. The extent to which diffractive loss at the  
28 waveguide end faces must be minimized (i.e., the operationally acceptable limits for  
29 diffractive loss for a given semiconductor optical device application) may determine  
30 what, if any, measures may be desirable, necessary, and/or warranted for its

1 minimization. The added cost and complexity of such measures may be similarly  
2 determinative.

3 **[0079]** If relatively large end-coupling losses (up to 30% or even as much as about  
4 50%) due to diffraction are tolerable, then fabrication of waveguide layers 204, 206, and  
5 208 may be carried out using relatively non-directional deposition techniques (Fig. 7).  
6 The waveguide material(s) deposited on device waveguide end face 120 may be simply  
7 left in place, and the resulting diffractive loss at waveguide segment 201 tolerated. If  
8 the diffractive loss at waveguide segment 201 is too large for a given device, various  
9 adaptations and/or alternative processing schemes may be implemented for reducing it.

10 **[0080]** Diffractive loss at waveguide segment 201 may be reduced somewhat by  
11 reducing the thickness of lower cladding layer 208 of integrated waveguide 200, thereby  
12 also reducing the thickness of cladding material on end face 120 and the length of the  
13 unconfined waveguide segment 201. This reduction of the lower waveguide cladding  
14 layer may be sufficient to reduce the diffractive loss to an operationally acceptable level.  
15 However, if the lower cladding 208 is too thin, then an unacceptably large fraction of the  
16 optical power propagating through waveguide 200 may leak into semiconductor  
17 substrate 102 and be lost, the semiconductor substrate 102 typically having a refractive  
18 index larger than the core or cladding layers of integrated waveguide 200. A thin  
19 reflective film 203 (metal, multilayer, or other reflective film) may be deposited on the  
20 substrate 102 prior to deposition of waveguide lower cladding layer 208 (Fig. 17),  
21 thereby reducing or substantially eliminating optical loss due to substrate leakage. If the  
22 lower cladding layer 208 is too thin, however, the reflective coating 203 may itself cause  
23 optical loss along waveguide 200 (by optical absorption by a metal coating, for  
24 example). As an illustrative example, an optical mode about 1  $\mu\text{m}$  high by about 2  $\mu\text{m}$   
25 wide supported by a thin silicon nitride core (about 100 nm thick) with a lower cladding  
26 layer about 2  $\mu\text{m}$  thick results in optical loss though substrate leakage less than about  
27 10 dB/cm (within operationally acceptable limits in many circumstances), but also  
28 results in a 2  $\mu\text{m}$  thick layer of cladding material on the laser end face. Addition of a thin  
29 metal film reflector layer 203 and reduction of the lower cladding layer to about 1  $\mu\text{m}$   
30 thick also results in optical loss of about 10 dB/cm, but with only about a 1  $\mu\text{m}$  thick  
31 layer of cladding material on the semiconductor end face (and correspondingly less

1 diffractive loss). Further reduction in the lower cladding thickness results in further  
2 reduction of diffraction loss at the proximal end of waveguide 200, but increases the  
3 optical loss upon propagation along waveguide 200. Spatially selective material  
4 processing may be employed for depositing metal reflector layer 203 without deposition  
5 on device end face 120. As shown on Fig. 18, the thickness of metal reflective layer  
6 203 may be chosen to substantially match the thickness of optical coating layer(s) 122  
7 applied to end face 120 (and typical also to an adjacent portion of substrate 102),  
8 thereby providing a substantially flat surface on which to form integrated waveguide  
9 200.

10 **[0081]** A thin film reflector may prove advantageous in other circumstances as well. In  
11 the transverse-coupled embodiments of Figs. 14A/14B and 15A/15B, use of a tapered  
12 and terminated core is often employed for achieving substantially adiabatic transverse-  
13 transfer between an integrated waveguide and a fiber-optic taper segment or planar  
14 waveguide assembled therewith. Testing and "burn-in" of semiconductor optical  
15 devices (including semiconductor lasers) is typically carried out before assembly with  
16 the fiber-optical taper or waveguide, but without such a transverse-coupled component,  
17 once beyond the end of the core the laser power would typically diverge and be at least  
18 partially lost into the substrate. Monitoring and accurately measuring the optical output  
19 power under such circumstances is difficult, and dissipation of significant levels of laser  
20 power within substrate 302 may have undesirable consequences (such as damage to  
21 the semiconductor device). By adding a thin film reflector layer between the device  
22 substrate and the integrated waveguide, loss of optical power into the device substrate  
23 may be reduced or substantially eliminated, and a larger fraction of the optical power  
24 may be measured and monitored as it exits a distal end face of the integrated  
25 waveguide.

26 **[0082]** The end segment of waveguide 201 that lacks substantially complete  
27 transverse confinement may be substantially eliminated through additional spatially  
28 selective material processing steps. As shown in Fig. 19A, after formation of device  
29 waveguide end face 120, any needed/desired coating thereof (not shown), and any  
30 needed/desired metal reflective layer (not shown) on the substrate 102, lower cladding  
31 layer 208 is deposited as described hereinabove, with cladding material also deposited

1 on end face 120. Etch mask layer 210 may be deposited over the lower cladding layer  
2 208, while leaving exposed the cladding material on end face 120 (also typically leaving  
3 exposed cladding material deposited on top of device waveguide 100). The exposed  
4 cladding material is then etched down to a remaining thickness substantially matching  
5 the thickness of the masked cladding material. After mask removal, a substantially flat  
6 lower cladding layer 208 remains, with unwanted cladding material removed from end  
7 face 120. A similar sequence of deposition, masking, etching, and de-masking steps  
8 (represented by the three dots in Fig. 19A) may be employed for depositing waveguide  
9 core layer 204 while removing unwanted core material from the semiconductor device  
10 end face, and then upper waveguide cladding layer 206 may be deposited. The  
11 integrated end-coupled waveguide 200 thus formed provides substantial transverse  
12 optical confinement extending to device waveguide end face 120, thereby reducing or  
13 substantially eliminating diffractive optical loss. For an integrated end-coupled  
14 waveguide 200 having a relatively thin core layer 204 (on the order of a few hundred nm  
15 thick or less), it may be possible to leave core material on end face 120 without  
16 introducing substantial diffractive optical loss, owing to the thinness of the deposited  
17 layer.

18 **[0083]** Another exemplary process for forming an integrated end-coupled waveguide  
19 for a semiconductor optical device is shown in Fig. 35. After forming semiconductor  
20 optical device 100, a layer of cladding material 208 is deposited on substrate 102 and  
21 over an end portion of device 100. The thickness of cladding layer 208 above the  
22 substrate should be at least as large as the height of device 100, as shown in the first  
23 stage of the process diagram of Fig. 35. Chemical-mechanical polishing (CMP) is then  
24 employed to remove cladding material and yield a cladding material upper surface  
25 substantially flush with the device upper surface (as shown in second stage of Fig.35).  
26 Any suitable CMP process(es) may be employed. Such processes may be terminated  
27 when the top of device 100 is reached, or may in some instances remove some material  
28 from the top of device 100 in addition to cladding layer material. The remaining  
29 cladding material layer 208 has a substantially flat upper surface. A material-specific  
30 non-directional etch process may then be employed to reduce the thickness of the  
31 remaining cladding material layer 208 to a desired thickness for the lower cladding of

1 waveguide 200, while exposing a portion of the etched device end face and maintaining  
2 a substantially flat upper surface for the cladding material layer up to the end face (as in  
3 the third stage of Fig. 35). Deposition of core material layer 206 and upper cladding  
4 layer 204 may then be performed as described hereinabove, with core and cladding  
5 material deposited on the lower cladding layer 208, the device end face, and an end  
6 portion of device 100. At one or more stages of the process of Fig. 35, one or more of  
7 layers 204, 206, and/or 208 and/or device 100 is spatially-selectively processed in any  
8 suitable manner for providing lateral optical confinement for optical device 100 and/or  
9 integrated waveguide 200.

10 **[0084]** By depositing waveguide core material layer 204 on a substantially flat upper  
11 surface of layer 208, the waveguide core material extends to the device end face. The  
12 segment 201 of integrated waveguide 200 lacking complete transverse optical  
13 confinement is reduced relative to an integrated waveguide produced by the procedure  
14 of Fig. 7 (wherein lower cladding material is deposited on the device end face and the  
15 core does not reach the end face). A non-confined segment 201 of an integrated  
16 waveguide 200 formed by the procedure of Fig. 35 will be about as long as the core  
17 material deposited on the end face is thick. For an integrated low-index waveguide  
18 having a low-profile or thin core, the core material layer on the device end face may be  
19 less than about 1  $\mu\text{m}$  thick for silica-based cores, or only a few hundred  $\mu\text{m}$  or less for  
20 silicon nitride or silicon oxynitride cores. Diffractive optical loss associated with such  
21 short non-confined waveguide segments may be substantially reduced relative to  
22 diffractive optical loss from an integrated waveguide fabricated by the procedure of Fig.  
23 7 having a non-confined segment several  $\mu\text{m}$  in length, at the expense of additional  
24 processing steps. If even smaller diffractive loss is needed or desired, CMP processing  
25 may be employed for forming core layer 204 to yield a substantially flat upper surface of  
26 the core extending to the device end face and removing excess core material from the  
27 device end face. Any non-confined segment 201 of waveguide 200 is thereby  
28 substantially eliminated (once again, at the expense of additional processing steps).

29 **[0085]** In some embodiments it may not be possible to completely eliminate the end  
30 segment 201 of the integrated end-coupled waveguide 200 that lacks substantially  
31 complete transverse optical confinement, or to reduce its length to a degree sufficient to

1 reduce diffractive losses below an operationally acceptable level. Even if possible, it  
2 may be undesirable, impractical, and/or unjustified to do so due to the additional  
3 spatially selective material processing steps required and the attendant increased cost  
4 and complexity of fabrication involved. In addition, spatially selective material  
5 processing steps required to produce device waveguide end face 120 with a sufficiently  
6 accurate surface profile and/or with sufficiently high optical quality may necessitate a  
7 laterally extending end face segment of device waveguide 100 (as shown in Fig. 2C),  
8 and substantially complete transverse optical confinement would be lacking in such a  
9 segment of device waveguide 100. Diffractive optical loss from waveguide segment(s)  
10 lacking substantially complete transverse optical confinement may be reduced or  
11 substantially eliminated by suitable adaptation(s) of the surface profile of device  
12 waveguide end face 120 and/or the proximal end of the integrated waveguide 200.

13 **[0086]** Diffractive optical loss from waveguide segment(s) lacking substantially  
14 complete transverse optical confinement may be reduced by suitable adaptation of the  
15 proximal segment of the integrated waveguide 200 to exploit the effect of multi-mode  
16 interference. Fig. 19B illustrates a fabrication sequence for forming integrated  
17 waveguide 200. After formation of device waveguide end face 120, any needed/desired  
18 coating thereof (not shown), and reflective layer 203 on the substrate 102, lower  
19 cladding layer 208 is deposited as described hereinabove, with cladding material also  
20 deposited on end face 120. Core 204 is then deposited; however, the proximal end of  
21 the core is displaced distally from the end face 120, leaving a waveguide segment 211  
22 of length L between the end face 120 and the proximal end of core 204 with no core  
23 layer. Upper cladding layer 206 is then deposited, comprising substantially the same  
24 material as the lower cladding layer 208.

25 **[0087]** The thicknesses of layers 208 and 206 and the width of waveguide segment  
26 211 are chosen so that the waveguide segment 211 forms a multi-mode waveguide  
27 segment (which lacks core 204), which differs from the remainder of the integrated  
28 waveguide (which includes core 204). The lowest order optical mode of each of the  
29 device waveguide 100 and the integrated waveguide 200 (including core 204) couple  
30 into respective superpositions of several of the lowest-order modes supported by multi-  
31 mode waveguide segment 211. Each of these lowest order modes propagates with its

own effective index (or propagation constant), so that the relative phases of the modes vary substantially linearly with propagation distance along waveguide segment 211. This variation of relative phases results in evolution of the transverse profile of the superposition along the length of multi-mode waveguide segment 211, due to constructive and destructive interference of varying portions of the modes as their relative phases vary. Modes of a given superposition that start out substantially in phase at one end of waveguide segment 211 become substantially in phase again at a specific distance along the waveguide segment 211 (referred to herein as a recurrence distance, which may be calculated based on the modal indices of the modes of the superposition). Core 204 is fabricated so that the length L of the waveguide segment 211 substantially corresponds to this recurrence distance (or an integer multiple thereof). The superposition corresponding to the device waveguide mode at end face 120 recurs at the proximal end of core 204, while the superposition corresponding to the integrated waveguide mode at the proximal end of core 204 recurs at end face 120. The overall end-coupling efficiency between the device waveguide and the integrated waveguide is therefore substantially determined by the degree to which the respective waveguide modes are spatial mode matched, thereby enabling reduction or substantial elimination of diffractive optical loss relative to the embodiments of Figs. 7, 17, and/or 18, for example. For optical modes of the typical sizes described herein, for example, the recurrence distance may be on the order of about 10 to 20  $\mu\text{m}$  in length, although this length range may vary widely depending on the specific characteristics of the device and integrated waveguides.

**[0088]** Implementation of the multi-mode interference scheme described in the preceding paragraph requires waveguide segment 211 to be designed and fabricated so that the modal indices are known with accuracy and precision sufficient to enable sufficiently accurate calculation of the recurrence length. Accordingly, the thicknesses and/or widths of cladding material layers 206/208 and the transverse optical confinement properties thereof, must be designed and fabricated sufficiently accurately and precisely. Vertical optical confinement within waveguide segment 211, if present, may be provided in any suitable manner. Reflective layer 203 (metal, multi-layer, or other suitable reflective layer) may be employed for providing well-defined optical

1 confinement from below waveguide segment 211. An upper reflective coating (not  
2 shown) may be deposited over upper cladding layer 206 for providing similarly well-  
3 defined optical confinement from above waveguide segment 211. Index contrast  
4 between upper cladding layer 206 and its surroundings (air, vacuum, encapsulation  
5 material, a lower-index secondary cladding layer, etc) may instead be relied upon for  
6 optical confinement from above, if sufficiently well-characterized for enabling sufficiently  
7 accurate calculation of modal indices. Index contrast between lower cladding layer 208  
8 and a lower-index secondary cladding layer (between lower cladding 208 and substrate  
9 102; not shown) may instead be relied on for optical confinement from below, if  
10 sufficiently well-characterized for enabling sufficiently accurate calculation of modal  
11 indices. Lateral optical confinement within waveguide segment 211, if present, may be  
12 provided in any suitable manner, such as reflective coatings applied to lateral surfaces  
13 of waveguide segment 211, index contrast between waveguide segment 211 and its  
14 surroundings (air, vacuum, encapsulation material, lateral secondary cladding material,  
15 etc), index contrast between medial and lateral portions of waveguide segment 211, and  
16 so forth, providing such lateral optical confinement is sufficiently well-characterized for  
17 enabling sufficiently accurate calculation of modal indices.

18 **[0089]** Multi-mode interference may also be exploited to form a mode expander. The  
19 incident optical mode may couple into multiple modes of the multimode waveguide  
20 segment, the incident superposition thus formed presumably being substantially smaller  
21 than the lowest-order modes of the superposition (at the incident end of the multi-mode  
22 waveguide segment). This incident superposition evolves spatially as it propagates  
23 along the multi-mode waveguide segment (as described hereinabove, due to differing  
24 modal propagation constants), and periodically recurs at regular spatial intervals along  
25 the multi-mode waveguide segment. Placing an incident end of a receiving waveguide  
26 (integrated waveguide 200 in the preceding examples) at one of these recurrence points  
27 is substantially equivalent to placing the incident end of the receiving waveguide in  
28 place of the incident end of the multi-mode waveguide segment, and may reduce or  
29 substantially eliminate diffractive losses (as already described hereinabove). At one or  
30 more points along a multi-mode waveguide segment between successive recurrences  
31 of the incident superposition, the modal superposition goes through a maximum

1 transverse size. If an incident end of a receiving waveguide is placed at such a  
2 maximum, then the multi-mode waveguide segment acts as a mode expander. Since  
3 all modes of the superposition cannot be simultaneously spatial-mode matched with a  
4 single mode of the receiving waveguide, such a multi-mode-interference-based mode  
5 expander may not typically provide coupling efficiencies as large as those attainable  
6 using a single-mode, substantially adiabatic mode expander. However, a multi-mode  
7 interference-based mode expander may provide a given degree of mode expansion  
8 over a substantially shorter propagation length than an equivalent single-mode  
9 expander. Differing design constraints for a mode expander (smaller size vs. higher  
10 coupling efficiency) may dictate which type of beam expander might be employed  
11 (multi-mode vs. single mode). Adaptations described hereinabove for reducing or  
12 substantially eliminating leakage of an expanded optical mode from a waveguide into an  
13 underlying substrate may be implemented for a multi-mode expander as well.

14 **[0090]** Diffractive optical loss from waveguide segment(s) lacking substantially  
15 complete transverse optical confinement may be reduced by suitable adaptation of the  
16 surface profile of device waveguide end face 120. Adaptation of the surface profile of  
17 device waveguide end face 120 may be implemented for achieving other purposes as  
18 well. Various surface profiles may be provided for end face 120. A substantially planar  
19 end face 120 may be provided, and the end face may be substantially vertical and  
20 substantially normal to the propagation direction supported at the end of the  
21 semiconductor device waveguide 100 (Figs. 1A/1B). A planar end face 120 may be  
22 provided that is not normal to this propagation direction, if needed or desired, so that  
23 any reflection from the end face 120 does not propagate back through the device  
24 waveguide structure. This may be particularly relevant for reducing reflective feedback  
25 into a semiconductor laser waveguide from the end face. For many spatially-selective  
26 material processing techniques, such a non-normal substantially planar end face may  
27 be most readily provided tilted horizontally (Figs. 20A/20B). Other spatially selective  
28 material processing techniques (including but not limited to anisotropic or directional  
29 etching, gray-scale lithography, or other suitable technique(s)) may be employed so as  
30 to form a non-normal substantially planar end face tilted in a vertical direction (Figs.  
31 21A/21B). A non-normal end face 120 may be provided tilted in both horizontal and

1 vertical directions (not shown). If a non-normal end face 120 is provided for device  
2 waveguide 100, refraction at the end face must be accounted for when designing the  
3 proper position and orientation of integrated end-coupled waveguide 200. In general, if  
4 the end face 120 is non-normal, then the waveguides 100 and 200 will not be collinear  
5 (Fig. 22).

6 **[0091]** A device end face 120 may be employed wherein at least a portion of the end  
7 face is curved in at least one dimension, for altering the convergence/ divergence  
8 properties of optical modes transmitted through and/or reflected from the device end  
9 face 120. For example, a convex device waveguide end face 120 may serve to reduce  
10 the divergence of, or to make convergent, an optical mode transmitted from the device  
11 waveguide 100 into an end-coupled integrated waveguide 200 of lower refractive index  
12 (Figs. 23A, 23B, 24, 25, 26, and 27), thereby increasing optical end-coupling relative to  
13 a flat end face. Therefore, suitable design of such a convex waveguide end face may  
14 be employed to reduce or substantially eliminate diffractive optical loss from waveguide  
15 segments lacking substantially complete transverse optical confinement. In another  
16 example, such a convex end face may serve as a concave reflector for coupling a  
17 device optical mode back into the device (as a laser end mirror, for instance). In either  
18 of the preceding examples, the curved portion of the end face may be limited in  
19 transverse extent (Fig. 23B), so as to suppress end-coupling and/or reflective coupling  
20 of higher-order device optical modes. If needed or desired, lateral portions of the end  
21 face may also be tilted away from normal (as in Fig. 23B) or otherwise adapted for  
22 suppressing end-coupling and/or reflective coupling of such higher-order modes. In  
23 other examples, a concave end face 120 might be employed if appropriate (Figs. 28 and  
24 29). A curved end face 120 may be aligned substantially normal to the propagation  
25 direction supported at the end of the semiconductor device waveguide 100, in which  
26 case the adjacent ends of device waveguide 100 and integrated end-coupled  
27 waveguide 200 may be substantially collinear (Figs. 23A, 23B, 24, 28, and 29).  
28 Alternatively, a curved end face 120 may be non-normal (tilted horizontally and/or  
29 vertically as in Figs. 25, 26, and 27; see discussion hereinabove), in which case the  
30 device waveguide 100 and integrated end-coupled waveguide 200 would be non-  
31 collinear so as to compensate for refraction at non-normal end face 120 (Fig. 25). For

1 many spatially-selective material processing techniques, a curved surface profile for end  
2 face 120 may be most readily provided curved in the horizontal dimension (Figs. 23A,  
3 23B, 24, 25, 28, and 29). Other spatially selective material processing techniques  
4 (including but not limited to anisotropic or directional etching, gray-scale lithography, or  
5 other suitable technique(s)) may be employed so as to form a curved surface profile for  
6 end face 120 curved in the vertical dimension (Figs. 26, 27, and 29). A curved surface  
7 profile for end face 120 may be provided curved in both horizontal and vertical  
8 dimensions (not shown).

9 **[0092]** Multi-mode interference and a curved waveguide end face may be implemented  
10 together for reducing diffractive optical loss from waveguide segments lacking  
11 substantially complete transverse optical confinement. For example, diffractive optical  
12 loss in the vertical direction may be reduced or substantially eliminated using multi-  
13 mode interference, by suitable configuration of an intermediate multi-mode waveguide  
14 segment (as described hereinabove) along the vertical dimension. In addition, the  
15 waveguide end face may also be suitably curved in the horizontal dimension so as to  
16 reduce or substantially eliminate diffractive optical loss in the horizontal direction.

17 **[0093]** In addition to, or instead of, a curved end face 120, device waveguide 100 may  
18 be provided with a flared end segment thereof 124 (Fig. 30). A flared end segment 124  
19 for waveguide 100 may in some circumstances more readily enable substantial spatial  
20 mode matching with waveguide 200, either directly end-coupled (and perhaps including  
21 an intervening waveguide segments lacking substantially complete transverse optical  
22 confinement) or end-coupled through multi-mode interference (as described  
23 hereinabove). The resulting enlarged optical mode supported by the flared end of the  
24 device waveguide may be correspondingly less divergent upon propagation through  
25 waveguide segment(s) lacking substantially complete transverse optical confinement,  
26 with correspondingly less diffractive optical loss. The flared waveguide end should flare  
27 substantially adiabatically (i.e., sufficiently gradually so as to maintain coupling of optical  
28 power into unwanted waveguide modes at or below operationally acceptable levels).  
29 For many spatially-selective material processing techniques, a flared end 124 for device  
30 waveguide 100 may be more readily provided flared in the horizontal dimension (Fig.  
31 30). Other spatially selective material processing techniques (including but not limited

1 to anisotropic or directional etching, gray-scale lithography, or other suitable  
2 technique(s)) may be employed so as to form a flared end 124 for waveguide 100 flared  
3 in the vertical dimension (not shown). Device waveguide 100 may have a flared end  
4 124 flared in both horizontal and vertical dimensions (not shown).

5 **[0094]** A variety of adaptations for the structure of device waveguide 100 and end face  
6 120 thereof, and for integrated end-coupled waveguide 200, have been set forth  
7 hereinabove, which may be implemented singly or in combination for providing  
8 efficiency for optical end-transfer between waveguide 100 and 200 at or above an  
9 operationally acceptable level. An operationally acceptable level of optical end-transfer  
10 efficiency (i.e., sufficiently high efficiency, or equivalently, sufficiently low optical loss)  
11 may be determined by the performance required of a device in a particular application,  
12 as well as considerations of cost and complexity of manufacture. For example, in some  
13 instances more stringent optical device performance requirements may require/justify  
14 additional manufacturing steps, while in other instances device pricing pressures may  
15 require elimination of manufacturing steps at the expense of lowered device  
16 performance characteristics.

17 **[0095]** For purposes of the foregoing written description and/or the appended claims,  
18 "index" may denote the bulk refractive index of a particular material (also referred to  
19 herein as a "material index") or may denote an "effective index"  $n_{eff}$ , related to the  
20 propagation constant  $\beta$  of a particular optical mode in a particular optical element by  $\beta =$   
21  $2\pi n_{eff}/\lambda$ . The effective index may also be referred to herein as a "modal index". As  
22 referred to herein, the term "low-index" shall denote any materials and/or optical  
23 structures having an index less than about 2.5, while "high-index" shall denote any  
24 materials and/or structures having an index greater than about 2.5. Within these  
25 bounds, "low-index" may refer to: silica ( $\text{SiO}_x$ ), germano-silicate, boro-silicate, other  
26 doped silicas, and/or other silica-based materials; silicon nitride ( $\text{Si}_x\text{N}_y$ ) and/or silicon  
27 oxynitrides ( $\text{SiO}_x\text{N}_y$ ); other glasses; other oxides; various polymers; and/or any other  
28 suitable optical materials having indices below about 2.5. "Low-index" may also include  
29 optical fiber, optical waveguides, planar optical waveguides, and/or any other optical  
30 components incorporating such materials and/or exhibiting a modal index below about  
31 2.5. Similarly, "high-index" may refer to materials such as semiconductors, IR materials,

1 and/or any other suitable optical materials having indices greater than about 2.5, and/or  
2 optical waveguides of any suitable type incorporating such material and/or exhibiting a  
3 modal index greater than about 2.5. The terms "low-index" and "high-index" are to be  
4 distinguished from the terms "lower-index" and "higher-index", also employed herein.  
5 "Low-index" and "high-index" refer to an absolute numerical value of the index (greater  
6 than or less than about 2.5), while "lower-index" and "higher-index" are relative terms  
7 indicating which of two particular materials has the larger index, regardless of the  
8 absolute numerical values of the indices.

9 **[0096]** The term "optical waveguide" (or equivalently, "waveguide") as employed herein  
10 shall denote a structure adapted for supporting one or more optical modes. Such  
11 waveguides shall typically provide confinement of a supported optical mode in two  
12 transverse dimensions while allowing propagation along a longitudinal dimension. The  
13 transverse and longitudinal dimensions/directions shall be defined locally for a curved  
14 waveguide; the absolute orientations of the transverse and longitudinal dimensions may  
15 therefore vary along the length of a curvilinear waveguide, for example. Examples of  
16 optical waveguides may include, without being limited to, various types of optical fiber  
17 and various types of planar waveguides. The term "planar optical waveguide" (or  
18 equivalently, "planar waveguide") as employed herein shall denote any optical  
19 waveguide that is provided on a substantially planar substrate. The longitudinal  
20 dimension (i.e., the propagation dimension) shall be considered substantially parallel to  
21 the substrate. A transverse dimension substantially parallel to the substrate may be  
22 referred to as a lateral or horizontal dimension, while a transverse dimension  
23 substantially perpendicular to the substrate may be referred to as a vertical dimension.  
24 Examples of such waveguides include ridge waveguides, buried waveguides,  
25 semiconductor waveguides, other high-index waveguides ("high-index" being above  
26 about 2.5), silica-based waveguides, polymer waveguides, other low-index waveguides  
27 ("low-index" being below about 2.5), core/clad type waveguides, multi-layer reflector  
28 (MLR) waveguides, metal-clad waveguides, air-guided waveguides, vacuum-guided  
29 waveguides, photonic crystal-based or photonic bandgap-based waveguides,  
30 waveguides incorporating electro-optic (EO) and/or electro-absorptive (EA) materials,  
31 waveguides incorporating non-linear-optical (NLO) materials, and myriad other

1 examples not explicitly set forth herein which may nevertheless fall within the scope of  
2 the present disclosure and/or appended claims. Many suitable substrate materials may  
3 be employed, including semiconductor, crystalline, silica or silica-based, other glasses,  
4 ceramic, metal, and myriad other examples not explicitly set forth herein which may  
5 nevertheless fall within the scope of the present disclosure and/or appended claims.

6 **[0097]** One exemplary type of planar optical waveguide that may be suitable for use  
7 with optical components disclosed herein is a so-called PLC waveguide (Planar  
8 Lightwave Circuit). Such waveguides typically comprise silica or silica-based  
9 waveguides (often ridge or buried waveguides; other waveguide configuration may also  
10 be employed) supported on a substantially planar silicon substrate (often with an  
11 interposed silica or silica-based optical buffer layer). Sets of one or more such  
12 waveguides may be referred to as planar waveguide circuits, optical integrated circuits,  
13 or opto-electronic integrated circuits. A PLC substrate with one or more PLC  
14 waveguides may be readily adapted for mounting one or more optical sources, lasers,  
15 modulators, and/or other optical devices adapted for end-transfer of optical power with a  
16 suitably adapted PLC waveguide. A PLC substrate with one or more PLC waveguides  
17 may be readily adapted (according to the teachings of U.S. Patent Application Pub. No.  
18 2003/0081902 and/or U.S. App. No. 60/466,799) for mounting one or more optical  
19 sources, lasers, modulators, photodetectors, and/or other optical devices adapted for  
20 transverse-transfer of optical power with a suitably adapted PLC waveguide (mode-  
21 interference-coupled, or substantially adiabatic, transverse-transfer; also referred to as  
22 transverse-coupling).

23 **[0098]** For purposes of the foregoing written description and/or appended claims,  
24 "spatially-selective material processing techniques" shall encompass epitaxy, layer  
25 growth, lithography, photolithography, evaporative deposition, sputtering, vapor  
26 deposition, chemical vapor deposition, beam deposition, beam-assisted deposition, ion  
27 beam deposition, ion-beam-assisted deposition, plasma-assisted deposition, wet  
28 etching, dry etching, ion etching (including reactive ion etching), ion milling, laser  
29 machining, spin deposition, spray-on deposition, electrochemical plating or deposition,  
30 electroless plating, photo-resists, UV curing and/or densification, micro-machining using  
31 precision saws and/or other mechanical cutting/shaping tools, selective metallization

1 and/or solder deposition, chemical-mechanical polishing for planarizing, any other  
2 suitable spatially-selective material processing techniques, combinations thereof, and/or  
3 functional equivalents thereof. In particular, it should be noted that any step involving  
4 “spatially-selectively providing” a layer or structure may involve either or both of:  
5 spatially-selective deposition and/or growth, or substantially uniform deposition and/or  
6 growth (over a given area) followed by spatially-selective removal. Any spatially-  
7 selective deposition, removal, or other process may be a so-called direct-write process,  
8 or may be a masked process. It should be noted that any “layer” referred to herein may  
9 comprise a substantially homogeneous material layer, or may comprise an  
10 inhomogeneous set of one or more material sub-layers. Spatially-selective material  
11 processing techniques may be implemented on a wafer scale for simultaneous  
12 fabrication/processing of multiple structures on a common substrate wafer.

13 **[0099]** The term “optical device” or “semiconductor optical device” as used herein may  
14 denote a device providing optical functionality (passive and/or active) wherein at least a  
15 portion of the device comprises suitably configured semiconductor material(s). The  
16 terms “device”, “optical device”, and/or “semiconductor optical device” as used herein  
17 may denote only the semiconductor portion of an optical device, or may denote an  
18 overall optical device structure or assembly of which only a portion comprises  
19 semiconductor material(s) (and which may include an integrated end-coupled  
20 waveguide as described further hereinbelow). Which of these is intended is typically  
21 evident from the context in which the term appears. The term “semiconductor laser” as  
22 used herein may denote a semiconductor optical device adapted for providing optical  
23 gain upon electrical pumping (i.e., a laser gain medium), or may alternatively refer to an  
24 optical resonator (supporting longitudinal optical modes) with such a semiconductor  
25 optical gain medium included therein. Which of these is intended is typically evident  
26 from the context in which the term appears.

27 **[0100]** It should be noted that various components, elements, structures, and/or layers  
28 described herein as “secured to”, “connected to”, “mounted on”, “deposited on”, “formed  
29 on”, “positioned on”, etc., a substrate may make direct contact with the substrate  
30 material, or may make contact with one or more layer(s) and/or other intermediate

1 structure(s) already present on the substrate, and may therefore be indirectly "secured  
2 to", etc, the substrate.

3 **[0101]** The phrase "operationally acceptable" appears herein describing levels of  
4 various performance parameters of optical components and/or optical devices, such as  
5 optical power transfer efficiency (equivalently, optical coupling efficiency), optical loss,  
6 undesirable reflection, and so on. An operationally acceptable level may be determined  
7 by any relevant set or subset of applicable constraints and/or requirements arising from  
8 the performance, fabrication, device yield, assembly, testing, availability, cost, supply,  
9 demand, and/or other factors surrounding the manufacture, deployment, and/or use of a  
10 particular optical component or assembly. Such "operationally acceptable" levels of  
11 such parameters may therefor vary within a given class of devices depending on such  
12 constraints and/or requirements. For example, a lower optical coupling efficiency may  
13 be an acceptable trade-off for achieving lower device fabrication costs in some  
14 instances, while higher optical coupling efficiency may be required in other instances in  
15 spite of higher fabrication costs. The "operationally acceptable" coupling efficiency  
16 therefore varies between the instances. Many examples of such trade-offs may be  
17 imagined, with correspondingly differing definitions of "operationally acceptable".  
18 Optical components, planar waveguides, and fabrication and/or assembly methods  
19 therefor as disclosed herein, and equivalents thereof, may therefore be implemented  
20 within tolerances of varying precision depending on such "operationally acceptable"  
21 constraints and/or requirements. Phrases such as "substantially spatial-mode-  
22 matched", "substantially index-matched", "so as to substantially avoid undesirable  
23 reflection", and so on as used herein shall be construed in light of this notion of  
24 "operationally acceptable" performance.

25 **[0102]** While particular examples have been disclosed herein employing specific  
26 materials and/or material combinations and having particular dimensions and  
27 configurations, it should be understood that many materials and/or material  
28 combinations may be employed in any of a variety of dimensions and/or configurations  
29 while remaining within the scope of inventive concepts disclosed and/or claimed herein.  
30 It should be pointed out that while wafer-scale processing sequences are set forth as  
31 examples, any or all of the processing sequences set forth herein, and/or equivalents

1    thereof, may also be implemented for smaller sets of components, or for individual  
2    components, while remaining within the scope of the present disclosure and/or  
3    appended claims. It is intended that equivalents of the disclosed exemplary  
4    embodiments and methods shall fall within the scope of the present disclosure and/or  
5    appended claims. It is intended that the disclosed exemplary embodiments and  
6    methods, and equivalents thereof, may be modified while remaining within the scope of  
7    the present disclosure and/or appended claims.
